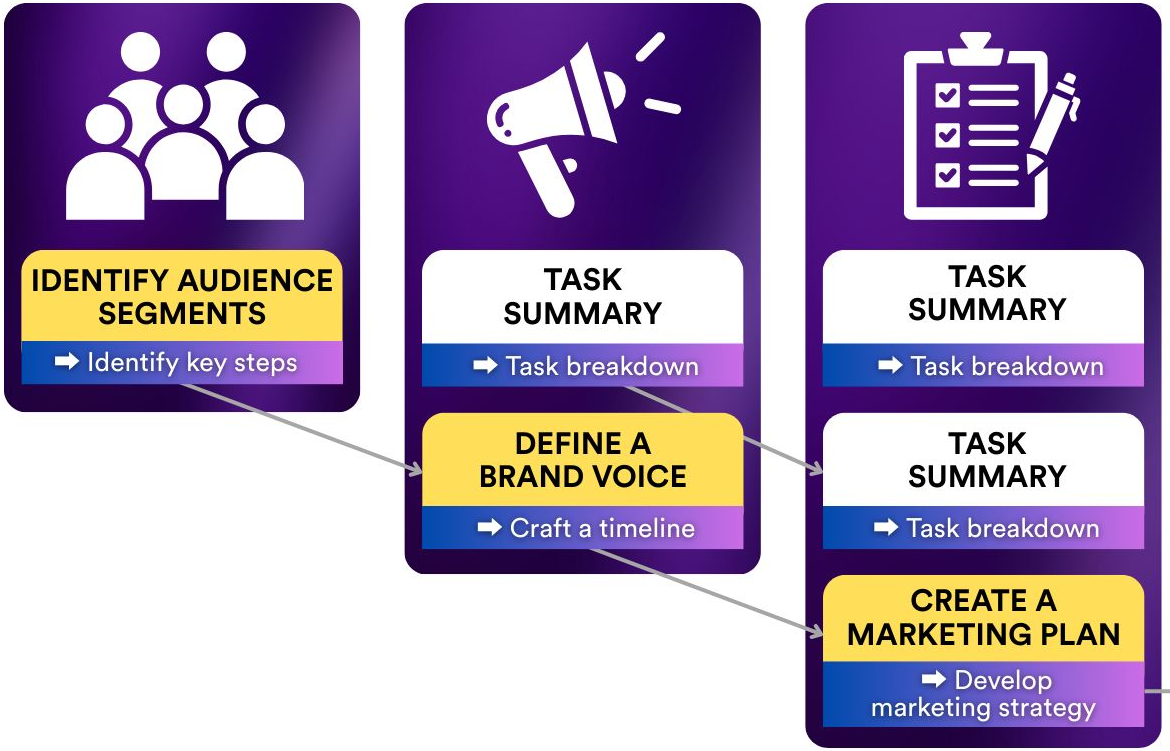
Introducing Sam and His Use Case

- To make these concepts more relatable, let's meet Sam, a freelance marketing consultant helping small businesses
- In the following examples, Sam will be using AI to create a product launch plan for a new line of smart home security cameras
- This scenario will help guide our exploration of different prompting frameworks
- Let's dive into how these techniques can take your prompting skills to the next level

Prompt Chaining

- This framework breaks a task into smaller steps, using the output from one prompt as input for the next
- For Sam's product launch, he can start by asking ChatGPT to summarize key steps, then build on that with more detailed tasks like creating a timeline and writing marketing strategies
- Each step builds on the last for a well-structured and coherent plan
- This framework gives users more control over each piece of the task.

PROMPT CHAINING



PURPOSE

Turn big ideas into easy, manageable actions.

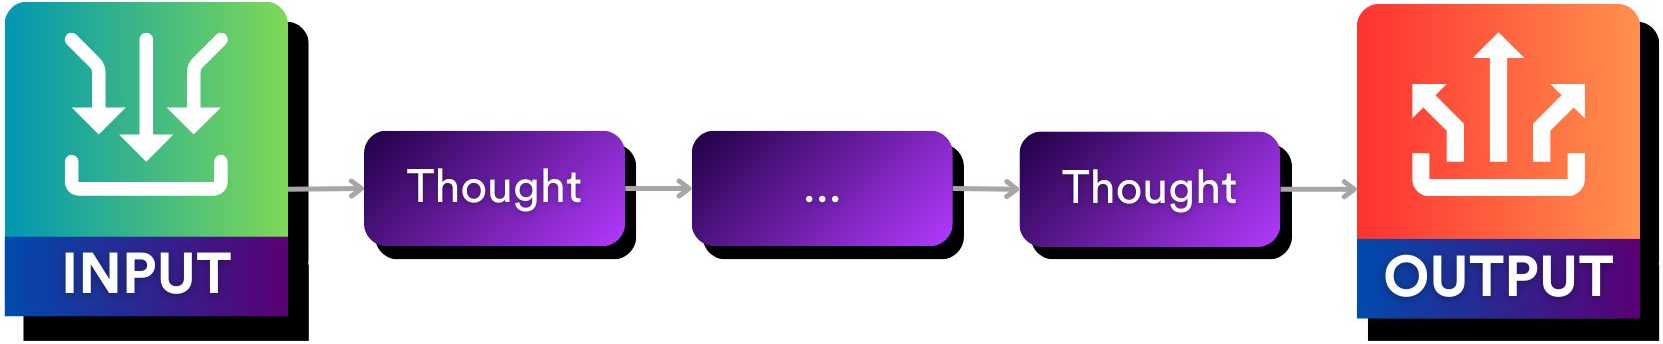
BEST USE CASES

Master complex projects with a clear, step-by-step flow.

Chain of Thought Reasoning

- This approach involves asking AI to think through a task step-by-step, making sure each part is well-reasoned
- By explaining why each element is important, the process becomes clearer and more logical
- Sam can use this method to understand the key components of his product launch and why they matter, leading to a well-reasoned and comprehensive plan

CHAIN OF THOUGHT REASONING



PURPOSE

Guide the AI to think through the problem clearly.

BEST USE CASES

Great for strategy, planning, and problem-solving.

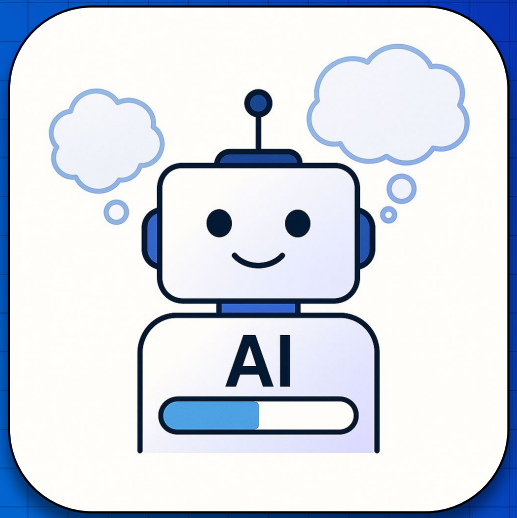
Building Smarter Responses

- Reasoning models take a similar approach to frameworks like Chain of Thought and Tree of Thought

- These models pause before responding, taking the time to think logically and structure their output. This results in more well-reasoned, higher-quality responses even when the prompt is simple

- Don’t worry if you’re not familiar with reasoning models just yet—they’ll be explained in more depth later

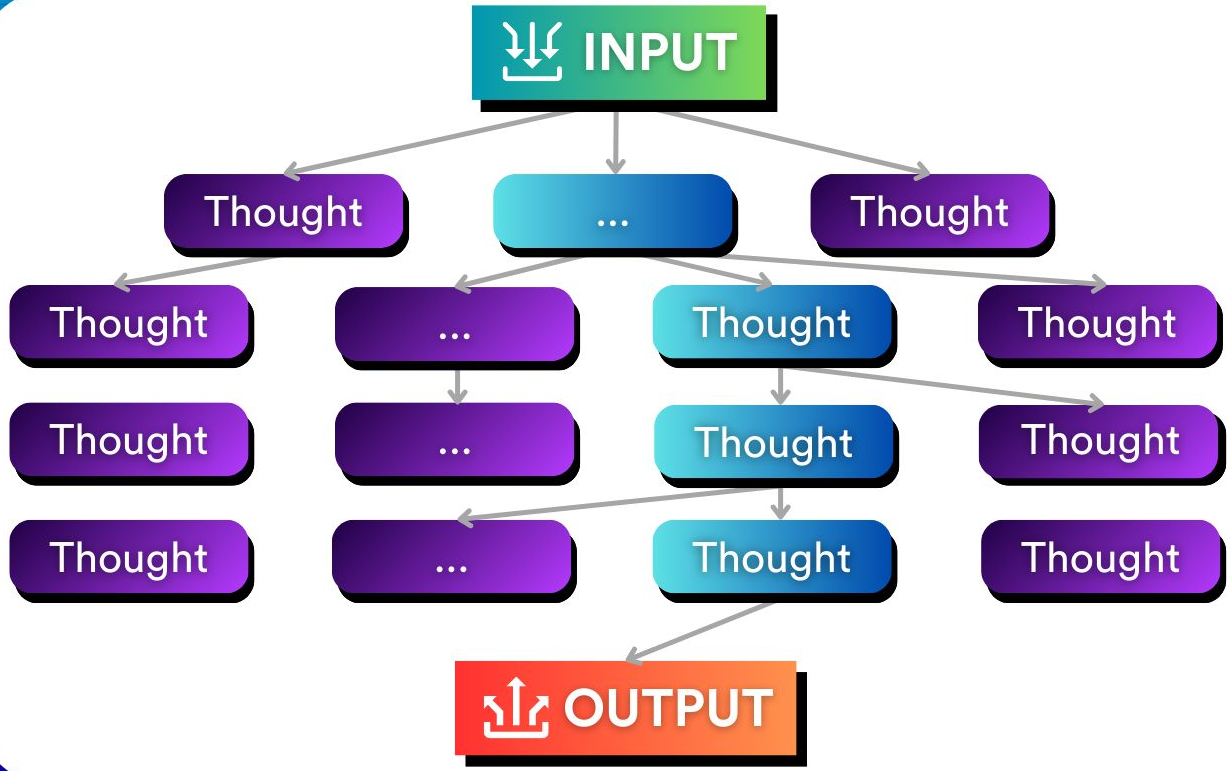
- Just know that the frameworks you’re learning here are the building blocks behind some of the smartest AI tools out there



Tree of Thought Reasoning

- Here, multiple ideas are explored before settling on the best option
- It’s perfect for tasks that require creative exploration and evaluating various possibilities
- In Sam's scenario, this can be used to brainstorm different strategies for his launch, giving him a range of ideas to refine before choosing the most suitable one

TREE OF THOUGHT REASONING



PURPOSE

Explore multiple paths, then choose the best.

BEST USE CASES

Perfect for brainstorming and strategic decisions.

Ask Before Answering

- With Ask Before Answering, ChatGPT asks clarifying questions before giving a response

- For example:
  "Before responding, ask me any clarifying questions about the target market, the product features, or any specific launch goals to better understand what I want."

- Sam uses this to ensure the AI fully understands the context that's relevant for the instructions provided

- This helps make the final plan more relevant and tailored to the business's needs.

Self-Critique Prompting

- In this method, the AI model critiques its own work after generating an output, making improvements for clarity, structure, and relevance

- For example:
  "Write a product launch plan for smart home security cameras. Then, critique the plan for clarity, structure, and relevance, and suggest improvements."

- For Sam's product launch plan, he can ask the AI to write a draft and then critique it for clarity, structure, and relevance

- This is a great way to get a polished and high-quality result before finalizing it

Decision Matrix Generation

- A decision matrix helps compare multiple options across different criteria

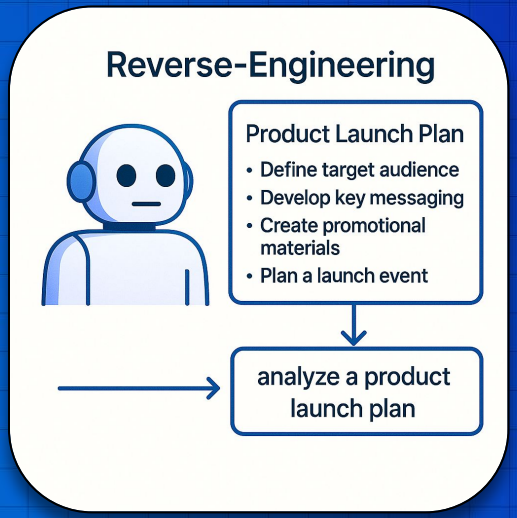
- For example:
  "***Create a decision matrix comparing three marketing strategies (social media, email campaigns, and influencer partnerships) for a smart home security camera product launch. Compare them based on cost, reach, and potential ROI***"

- Which can be valuable in Sam's use case in order to evaluate different marketing strategies, comparing factors like cost, reach, and potential ROI

- This framework provides a visual comparison, helping users make a more informed decision based on multiple factors

Reverse Prompt Engineering

- This approach involves analyzing a finished output to figure out which prompt generated it

- For example:
  "Here is the product launch plan for the smart home security cameras. Reverse engineer it to come up with the most likely prompt to have created this plan."


- Allowing our Avatar to work backward from a successful product launch plan, understanding the key elements of the prompt that led to the output
